

Module 12

Python Memory

The Problem of Methods

- Introduced objects in previous video seires
 - “Folders” with variables and functions
 - Called **attributes** and **methods**
- But we saw that strings also have methods

Are strings objects?

Surprise: All Values are in Objects!

- Including basic values
 - int, float, bool, str

Heap primitives Use arrows

- **Example:**

```
>>> x = 1000
```

```
>>> id(x)
```

This Explains A Lot of Things

- Primitives act like classes
 - Conversion function is really a constructor
 - Remember constructor, type have same name

- Example:

```
>>> type(1)
```

```
<class 'int'>
```

```
>>> int('1')
```

```
1
```

- Design goals of Python 3
 - Wanted everything an object
 - Makes processing cleaner
- But makes learning harder
 - Objects are complex topic
 - Want to delay if possible

But Not Helpful to Think This Way

- Number folders are **immutable**
 - “Attributes” have no names
 - No way to reach in folder
 - No way to change contents

x 4497040368

Makes a brand new int folder

```
>>> x = 1000
```

```
>>> y = 1000
```

```
>>> id(x)
```

```
4497040368
```

```
>>> id(y)
```

```
4497040400
```

```
>>> y = y+1
```

```
>>> id(y)
```

```
4497040432
```

But Not Helpful to Think This Way

- Number folders are **immutable**
 - “Attributes” have no names
 - No way to reach in folder
 - No way to change contents
 - Remember **purpose of folder**
 - Show how objects can be altered
 - Show how variables “share” data
 - This **cannot happen** in basic types
 - So just **ignore the folders**
 - (The are just metaphors anyway)
- ```
>>> x = 1000
>>> y = 1000
>>> id(x)
4497040368
>>> id(y)
4497040400
>>> y = y+1
>>> id(y)
4497040432
```

# Why Show All This?

---

- Many of these are **advanced topics**
  - Only advanced programmers need
  - Will never need in the context of 1110
- But you might use them by *accident*
- **Goal: Teach you to read error messages**
  - Need to understand what messages say
  - Only way to debug your own code

# The Three “Areas” of Memory

```
→ 1 def max(x,y):
 2 if x > y:
 3 return x
 4 return y
 5
 6 a = 1
 7 b = 2
→ 8 max(a,b)
```

[Edit code](#)

< Back

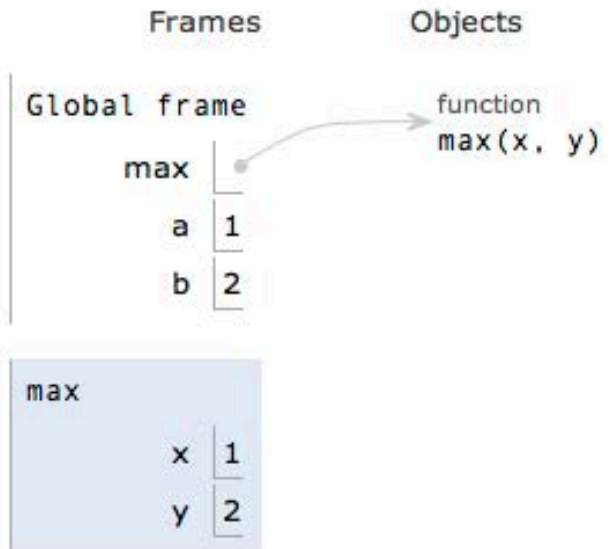

Step 5 of 8

Forward >

Global Space

Call Stack

Heap Space

# Global Space

---

- This is the **area you “start with”**
  - First memory area you learned to visualize
  - A place to store “global variables”
  - Lasts until you quit Python
- What are **global variables**?
  - **Any assignment not in a function definition**
  - Also **modules & functions!**
  - Will see more on this in a bit

p

id2

# The Call Stack

---

- The area **where call frames live**
  - Call frames are created on a function call
  - May be several frames (functions call functions)
  - Each frame deleted as the call completes
- Area of volatile, temporary memory
  - Less permanent than global space
  - Think of as “scratch” space
- Primary focus of Assignment 2

# Heap Space or “The Heap”

---

- **Where the “folders” live**
  - Stores *only* folders
- Can only **access indirectly**
  - Must have a variable with identifier
  - Can be in global space, call stack
- **MUST have variable with id**
  - If no variable has id, it is *forgotten*
  - Disappears in Tutor immediately
  - But not necessarily in practice
  - Role of the *garbage collector*

# Revisiting Modules

---

- Modules seem to behave a lot like objects
  - They can have *variables*: `math.pi`
  - Can even reassign these variables!
  - Function calls look like *methods*: `math.cos(1)`
- So are they also objects?
  - Said everything in Python is an object
- **Yes** (sort of)
  - Look same in memory, but created differently
  - Need to understand what happens on import

# Modules and Global Space

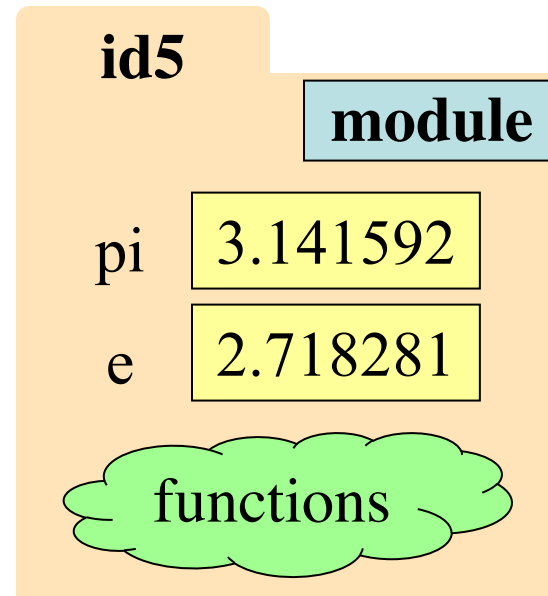

- Importing a module:
  - Creates a global variable (same name as module)
  - Puts contents in a **folder**
    - Module variables
    - Module functions
  - Puts folder id in variable
- Can reassign module var
- Tutor won't show contents

```
import math
```

**Global Space**

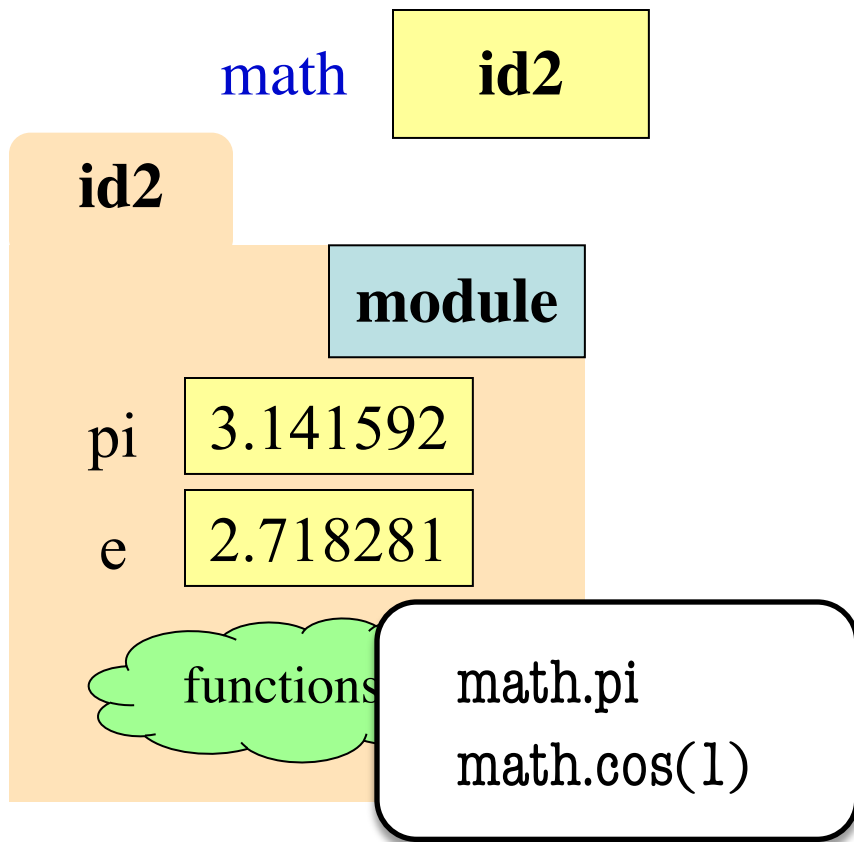

math **id5**

**Heap Space**

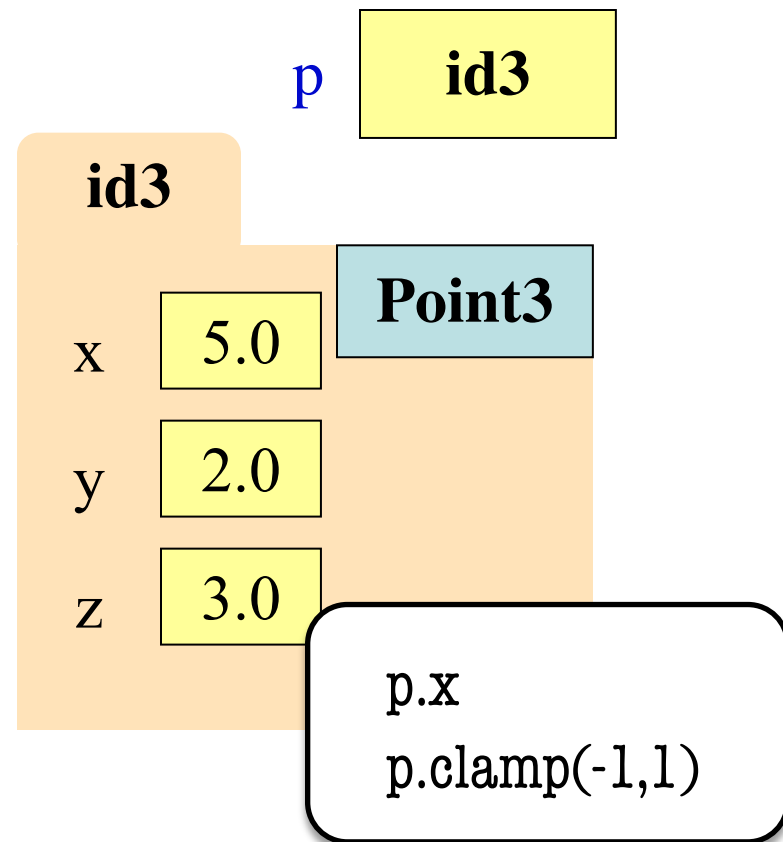

# Modules vs Objects

functions

math.pi  
math.cos(1)

p.x  
p.clamp(-1,1)

The period (.) means  
“go inside of the folder”

# So Why Have Both?

---

- Question is a matter of program design
  - Some software will use modules like objects
- Classes can have **many instances**
  - Infinitely many objects for the Point3 class
  - Reason we need a constructor function
- Each module is **a unique instance**
  - Only one possibility for pi, cosine
  - That is why we import them
  - Sometimes refer to as *singleton* objects

# So Why Have Both?

---

- Question is a matter of program design
  - Some software will use modules like objects
- Classes can have **many instances**
  - Infinitely many
  - Reusable
- Each **instance**
  - Only one possibility for pi, cosine
  - That is why we import them
  - Sometimes refer to as *singleton* objects

Choice is an advanced topic  
beyond scope of this course

# Are Functions Objects?

---

- “Everything an object” has major ramifications
  - Forced us to completely rethink modules
  - Anything else? What about functions?
- But functions live in the call stack!
  - Function **calls** live in the call stack
  - Remember there are two parts to a function
  - Where does the function *definition* live?
  - Python had to store the code somewhere
- If you are thinking objects, you are right

# Functions and Global Space

- A function definition...
  - Creates a global variable (same name as function)
  - Creates a **folder** for body
  - Puts folder id in variable

```
def to_centrigrade(x):
 return 5*(x-32)/9.0
```

Body

**Global Space**

to\_centrigrade **id6**

- Variable vs. Call

```
>>> to_centrigrade
```

```
<fun to_centrigrade at 0x100498de8>
```

```
>>> to_centrigrade (32)
```

```
0.0
```

**Heap Space**

id6

function

Body

# What Does Importing a Function Do?

Visualize   Execute Code   Edit Code

```
→ 1 from math import cos
→ 2 x = cos(1)
```

Step 2 of 2

<< First   < Back   Forward >   Last >>

→ line that has just executed  
→ next line to execute

Heap primitives  Use arrows

Just like  
defining it

# How About `import *`?

```
→ 1 from math import *
→ 2 x = cos(1)
```

<< First < Back Step 2 of 2 Forward > Last >>

Ouch!

# Working with Function Variables

---

- So function definitions are objects
  - Function names are just variables
  - Variable refers to a folder storing the code
  - If you reassign the variable, it is lost
- You can also assign them to other variables
  - Variable now refers to that function
  - You can use that **NEW** variable to call it
  - Just use variable in place of function name

# Example: add\_one

```
1 def add_one(x):
2 """Returns x+1"""
→ 3 return x+1
4
5 y = add_one
→ 6 z = y(2)
```

<< First < Back Step 4 of 5 Forward > Last >>

Globals

Objects

Frames

Frame remembers  
the original name

# Application: Functions as Parameters

---

```
def doit(f,arg):
```

```
 """Returns the result of the call f(arg)
```

```
 Param: f the function to call
```

```
 Precond: f a function that takes one argument
```

```
 Param arg: the function argument
```

```
 Precond: arg satisfies the precondition of f"""
```

```
 return f(arg)
```

Will see practical applications  
of this in a later video series

# Call Frames vs. Global Variables

The function does **nothing**:

```
1 def swap(a,b):
2 """Swap a & b"""
3 tmp = a
4 a = b
5 b = tmp
```

```
>>> a = 1
```

```
>>> b = 2
```

```
>>> swap(a,b)
```

Global Space

a **1**      b **2**

Call Frame

# Call Frames vs. Global Variables

The function does **nothing**:

```
1 def swap(a,b):
2 """Swap a & b"""
3 tmp = a
4 a = b
5 b = tmp
```

```
>>> a = 1
```

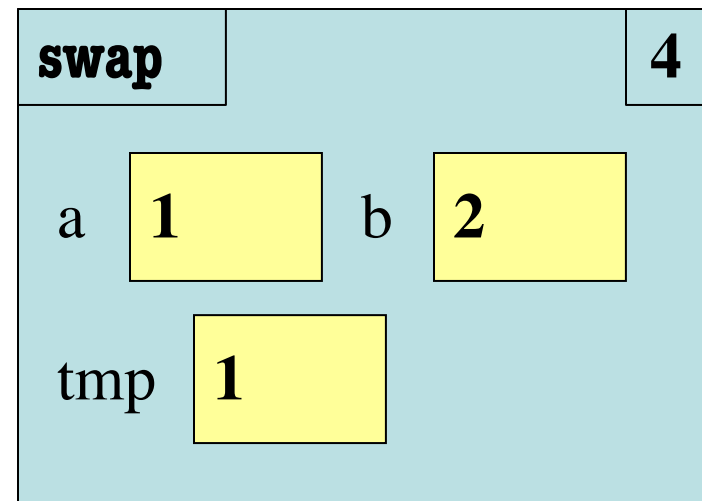

```
>>> b = 2
```

```
>>> swap(a,b)
```

Global Space

a **1**      b **2**

Call Frame

# Call Frames vs. Global Variables

The function does **nothing**:

```
1 def swap(a,b):
2 """Swap a & b"""
3 tmp = a
4 a = b
5 b = tmp
```

```
>>> a = 1
```

```
>>> b = 2
```

```
>>> swap(a,b)
```

Global Space

a 1 b 2

Call Frame

# Call Frames vs. Global Variables

The function does **nothing**:

```
1 def swap(a,b):
2 """Swap a & b"""
3 tmp = a
4 a = b
5 b = tmp
```

```
>>> a = 1
```

```
>>> b = 2
```

```
>>> swap(a,b)
```

Global Space

a 1 b 2

Call Frame

# Call Frames vs. Global Variables

---

The function does **nothing**:

```
1 def swap(a,b):
2 """Swap a & b"""
3 tmp = a
4 a = b
5 b = tmp
```

```
>>> a = 1
```

```
>>> b = 2
```

```
>>> swap(a,b)
```

Global Space

a 1    b 2

Call Frame

**ERASE THE FRAME**

# Functions **Can** Access Global Space

- Ways to use a global
  - Have to use in expression
  - **CANNOT** do assignment
- What happens if assign?
  - Makes a new local instead
  - Even if you assign it later
- So what use for globals?
  - Typically use as *constants*
  - **Example:** math.pi

```
8 a = 4 # global var
...
11 def get_a():
... |
15 | return a # global
```

# Functions Can Access Global Space

- Ways to use a global
  - Have to use in expression
  - **CANNOT** do assignment
- What happens if assign?
  - Makes a new local instead
  - Even if you assign it later
- So what use for globals?
  - Typically use as *constants*
  - **Example:** math.pi

```
18 def mask_a():
... |
... | ...
22 | a = 3.5
23 | return a # local
```

# The Global Keyword

- Possible to change global
  - Have to mark it as such
  - `global <variable>`
  - Should be at body start
- Use sparingly
  - Using globals is confusing
  - Easy to get lost
  - Best for constants

```
26 def change_a():
... """ """
... ...
30 global a
31 a = 3.5
32 return a # local
```

# Function Bodies Can Contain Other Calls

---

- We have seen this with print in greet
  - Does print have a call frame?
  - Yes, but cannot visualize (definition hidden)
- What happens when one calls another?
  - Have to create a new call frame
  - Old call frame **freezes** in place
  - Waits until second frame is erased
  - Then first frame continues again

# One Function Calling Another

---

```
1. def foo(x):
2. y = x+1
3. z = bar(y)
4. return z
5.
6. def bar(x):
7. y = x-1
8. return y
9.
10. w = foo(2)
```

Let's visualize  
ourselves first.  
(Tutor incomplete)

# One Function Calling Another
