# **CS 1110**

## **Prelim 1 Practice/Review Session**

# Announcements

- A3 due Sun Mar 28
- Prelim 1 Tues Mar 30 at 6:30pm in-person (university-scheduled)
  - Check CMS for your exam info if you requested alternate time/format
  - In-person: Bring pens/pencils/erasers (bring several). Bring a watch or even an actual clock if you have one. No smart watches/phones! You may not be able to see the wall clock in Barton from your seat. Bring Cornell ID.
  - Online: Your proctor will contact you about a mock exam. **You *must* do the mock exam** to be allowed to write the actual exam.
- Read Prelim 1 Study Guide. *Note spring different from fall.*
- Tues Mar 30 lecture and lab time → office hours
- Wedn Mar 31 no labs (so no new lab exercises next week)

# Exam Topics

---

- String slicing functions
- Call frames and the call stack
- Functions on mutable objects
- Testing and debugging
- Conditionals
- Lists and simple iteration

Dictionaries *not* on Prelim 1

Today:

- Start with *lists and iteration*—  
*not in posted old review slides*
- *Testing and debugging*
- *Other topics if time allows*

# Lists, Iteration, Strings

---

```
def count_non_space_chars(myList):
```

```
    """Returns: number of non-space characters in the strings in myList.
```

```
    Example: count_non_space_chars(['U', 'r', ", ' gr8']) returns 5
```

```
    Precondition: myList is a list of strings. Each string in myList can  
    contain only spaces, letters, digits."""
```

You *should know* the methods that we actually have used in assignments and labs. We will give you the less-frequently used methods on the exam.

```
def count_non_space_chars(myList):
```

```
    """Returns: number of non-space characters"""
```

```
    Example: count_non_space_chars(['U', 'r'])
```

```
    Precondition: myList is a list of strings.
```

```
    contain only spaces, letters, digits."""
```

```
    count = 0
```

```
    for s in myList:
```

```
        numSp = s.count(' ')
```

```
        numNonSp = len(s) - numSp
```

```
        count = count + numNonSp
```

```
    return count
```

### Remember:

- Be goal oriented—start with return statement (if it is needed). Work your way back up. Be flexible.
- Name a variable for any value you need but don't know yet
- For-loop
- Accumulation pattern
- How to call string methods

# Lists, Iteration, Types

---

def inflate(myList, p\_percent):

"""Inflate each number in myList by p\_percent while maintaining the type (int or float). For any int in myList, round down the inflation.

Precondition: myList is a list of positive numbers (int and/or float).

Precondition: p\_percent is a positive number (int or float)."""

An example:

```
>>> aList= [100, 100.0, 1, 1.0]
>>> p= 1.6
>>> inflate(aList,p)
>>> aList
[101, 101.6, 1, 1.016]
```

```
def inflate(myList, p_percent):
```

```
    """Inflate each number in myList by p_percent while maintaining the  
    type (int or float). For any int in myList, round down the inflation.
```

```
    Precondition: myList is a list of positive numbers (int and/or float).
```

```
    Precondition: p_percent is a positive number (int or float)."""
```

```
def inflate(myList, p_percent):
```

```
    """Inflate each number in myList by p_percent.  
    type (int or float). For any int in myList
```

```
    Precondition: myList is a list of positive numbers
```

```
    Precondition: p_percent is a positive number
```

```
    p_frac= p_percent/100
```

```
    for k in range(len(myList)):
```

```
        delta= myList[k]*p_frac
```

```
        if type(myList[k])==int:
```

```
            delta= int(delta)
```

```
        myList[k] += delta
```

### Remember:

- Give yourself an example if question doesn't provide one
- Using for-loop on list: do you need to modify list? If so you need the indices—use `range`
- List syntax
- How to work with types (ops, checking, casting)
- In general, read specs again after finishing code. Did you really solve problem asked?

# Constructing test cases

---

```
def before_space(s):
```

```
    """Returns: the substring before the first space character in string s.
```

```
    Precondition: string s contains at least one space."""
```

Come up with at least three *distinct* test cases. Write the test input, expected output, and rationale.

# Constructing test cases

---

```
def before_space(s):
```

```
    """Returns: the substring before the first space character in string s.  
    Precondition: string s contains at least one space."""
```

- First think about the pre-condition to see what we know about the string `s`
  - It has at least one space char → it can have more than one
    - adjacent? non-adjacent?
  - No precondition on where the space char appears in `s`
    - can be anywhere
      - start? middle? end?
- With these ideas, can construct distinct test cases with rationales for each one

# Constructing test cases

```
def before_space(s):
```

```
    """Returns: the substring before the first space character in string s.
```

```
    Precondition: string s contains at least one space."""
```

Examples:

- " abc" → "" – single space char at the start
- "abc " → "abc" – single space char at the end
- "a bc" → "a" – single space char in the “middle”  
(not start or end)
- " abc" → "" – many space chars at the start
- "abc " → "abc" – many space chars at the end
- "ab c" → "ab" – many space chars in the middle
- "a b c" → "a" – many non-adjacent space chars

# What should I be testing?

---

**Common Cases:** typical usage

**Edge Cases:** live at the boundaries

- **Target location in list:** first, middle, last elements
- **Input size:** 0,1,2, many (length of lists, strings, etc.)
- **Input Orders:** e.g., max(big, small), max(small, big)...
- **Element values:** negative/positive, zero, odd/even
- **Element types:** int, float, str, *etc.*
- **Expected results:** negative, 0, 1, 2, many

*Not all categories/cases apply to all functions.*

*Use your judgement!*

# Functions on Objects

---

- Class: **Rect**

- Constructor function: **Rect(x,y,width,height)**
- Remember constructor is just a function that gives us an object of that type and returns its identifier

- | Attribute | Description                         |
|-----------|-------------------------------------|
| x         | float, x coord of lower left corner |
| y         | float, y coord of lower left corner |
| width     | float, > 0, width of rectangle      |
| height    | float, > 0, height of rectangle     |

```
def move(r, xc, yc):
```

```
    """Set the attributes of Rect `r` such that its center lies on the x- and  
    y-coordinates `xc` and `yc`, respectively.
```

```
    Precondition: r is a Rect object.
```

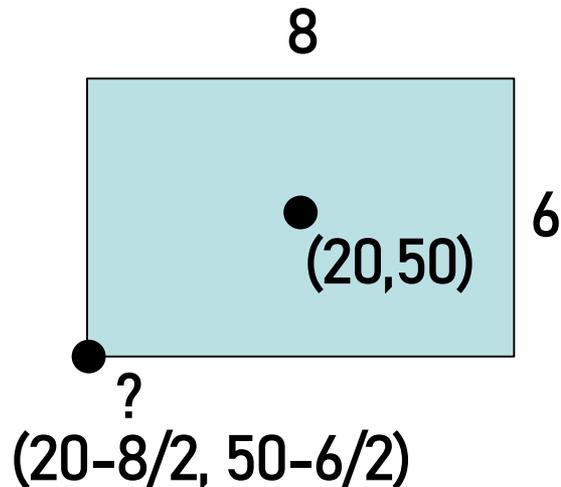

```
    Precondition: xc, yc are each a float."""
```

def move(r, xc, yc):

"""Set the attributes of Rect `r` such that its center lies on the x- and y-coordinates `xc` and `yc`, respectively.

Precondition: r is a Rect object.

Precondition: xc, yc are each a float."""

```
def move(r, xc, yc):
```

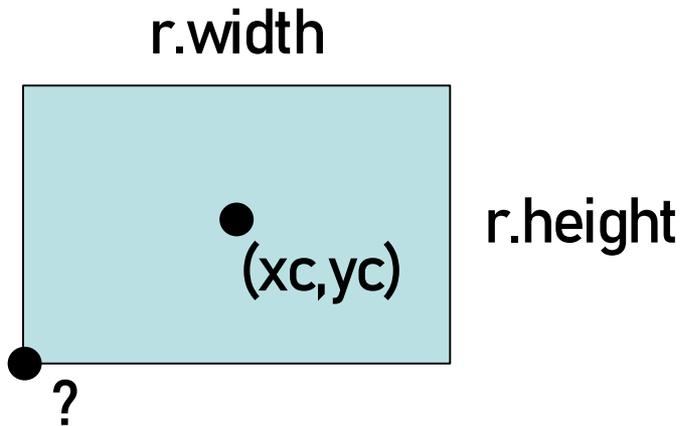

```
    """Set the attributes of Rect `r` so  
    y-coordinates `xc` and `yc`, respec
```

```
    Precondition: r is a Rect object.
```

```
    Precondition: xc, yc are each a f
```

$$r.x = xc - r.width/2$$

$$r.y = yc - r.height/2$$

### Remember:

- Draw a diagram to help yourself think
  - Label the diagram with example/known values. Then generalize labels using parameter and attribute names.
- ↩ Important problem solving step! First use example values to understand the problem and figure out relationships among knowns and unknowns.
- Dot-notation for accessing attributes of an object
